

A SUBFIELD LATTICE ATTACK ON OVERSTRETCHED NTRU ASSUMPTIONS

Martin R. Albrecht

Oxford Lattice School

OUTLINE

Introduction

Preliminaries

Subfield Lattice Attack

Martin Albrecht, Shi Bai, and Léo Ducas. *A subfield lattice attack on overstretched NTRU assumptions: Cryptanalysis of some FHE and Graded Encoding Schemes*. Cryptology ePrint Archive, Report 2016/127. <http://eprint.iacr.org/2016/127>. 2016

INTRODUCTION

Key Generation $\mathcal{R} = \mathbb{Z}[X]/(X^n + 1)$, modulus q , width parameter σ

- Sample $f \leftarrow D_{\mathcal{R},\sigma}$ (invertible mod q)
- Sample $g \leftarrow D_{\mathcal{R},\sigma}$
- Publish $h = [g/f]_q$

Encrypt $m \in \{0, 1\}^n$

- Sample $s, e \leftarrow D_{\mathcal{R},\chi}, D_{\mathcal{R},\chi}$
- Return $2(h \cdot s + e) + m$

Decrypt $c \in \mathcal{R}_q$

- $m' = f \cdot c = 2(g \cdot s + f \cdot e) + f \cdot m$
- Return $m' \bmod 2 \equiv f \cdot m \bmod 2$

THE NTRU LATTICE Λ_h^q

```
sage: K.<zeta> = CyclotomicField(8)
sage: OK = K.ring_of_integers()
sage: h = -36*zeta^3 + 44*zeta^2 + 14*zeta + 28
sage: h
```

$$-36\zeta_8^3 + 44\zeta_8^2 + 14\zeta_8 + 28$$

```
sage: H = h.matrix(); q = 97
sage: block_matrix([[1, H],[0, q]])
```

$$\left(\begin{array}{cccc|cccc} 1 & & & & 28 & 14 & 44 & -36 \\ & 1 & & & 36 & 28 & 14 & 44 \\ & & 1 & & -44 & 36 & 28 & 14 \\ & & & 1 & -14 & -44 & 36 & 28 \\ \hline & & & & 97 & & & \\ & & & & & 97 & & \\ & & & & & & 97 & \\ & & & & & & & 97 \end{array} \right)$$

THE NTRU LATTICE Λ_h^q

- The lattice Λ_h^q defined by an NTRU instance for parameters \mathcal{R}, q, σ has dimension $2n$ and volume q^n .
- If h were uniformly random, the Gaussian heuristic predicts that the shortest vectors of Λ_h^q have norm $\approx \sqrt{nq}$.
- Whenever

$$\|f\| \approx \|g\| \approx \sqrt{n} \sigma \ll \sqrt{nq},$$

then Λ_h^q has **unusually short vectors**.

Definition (NTRU Assumption)

It is hard to find a short vector in the \mathcal{R} -module

$$\Lambda_h^q = \{(x, y) \in \mathcal{R}^2 \text{ s.t. } hx - y = 0 \pmod{q}\}$$

with $\mathcal{R} = \mathbb{Z}[X]/(P(X))$ and the promise that a short solution (f, g) — the private key — exists.¹²

- Recovering a short enough vector of some target norm τ , potentially longer than (f, g) , is sufficient for an attack.⁶
- In particular, finding a vector $o(q)$ would break many applications such as encryption.
- This requires strong lattice reduction and NTRU remains asymptotically secure.^{7,8}

PRELIMINARIES

CYCLOTOMIC NUMBER FIELDS AND SUBFIELDS

- I'll focus on Cyclotomic number rings of degree $n = 2^k$ for ease of exposure, but everything can be made general.
- Let $\mathcal{R} \simeq \mathbb{Z}[X]/(X^n + 1)$ be the ring of integers of the Cyclotomic number field $\mathbb{K} = \mathbb{Q}(\zeta_m)$ for some $m = 2^k$ and $n = m/2$.
- Let $\mathbb{L} = \mathbb{Q}(\zeta_{m'})$ with $m'|m$ be a subfield of \mathbb{K} .
- The ring of integers of \mathbb{L} is $\mathcal{R}' \simeq \mathbb{Z}[X]/(X^{n'} + 1)$ with $n' = m'/2$.
- We write the canonical inclusion $\mathcal{R}' \subset \mathcal{R}$ explicitly as $L : \mathcal{R}' \rightarrow \mathcal{R}$.
- The norm $N_{\mathbb{K}/\mathbb{L}} : \mathbb{K} \rightarrow \mathbb{L}$ is the multiplicative map defined by

$$N_{\mathbb{K}/\mathbb{L}} : f \mapsto \prod_{\psi \in G'} \psi(f)$$

where G' is the Galois subgroup corresponding to \mathbb{L} .

The ring \mathcal{R} is viewed as a lattice by endowing it with the inner product

$$\langle a, b \rangle = \sum_{i=0}^{n-1} a_i \cdot b_i.$$

- This defines a Euclidean norm denoted by $\| \cdot \|$.
- We will make use of the operator's norm $| \cdot |$ defined by:

$$|a| = \sup_{x \in \mathbb{K}^*} \|ax\| / \|x\| = \max |a_i|.$$

- It holds that $\|a \cdot b\| \leq \sqrt{n} \cdot |a| \cdot \|b\|$ and

$$|N_{\mathbb{K}/\mathbb{L}}(a)| \leq \sqrt{n}^{r-1} |a|^r \leq \sqrt{n}^{r-1} \|a\|^r.$$

Lattice reduction algorithms produce vectors of length

$$\beta^{\Theta(n/\beta)} \cdot \lambda_1(\Lambda)$$

for a computational cost

$$\text{poly}(\lambda) \cdot 2^{\Theta(\beta)},$$

with $\lambda_1(\Lambda)$ the length of a shortest vector of Λ .¹³

SUBFIELD LATTICE ATTACK

OVERVIEW

1. NORMING DOWN

Define $f' = N_{\mathbb{K}/\mathbb{L}}(f)$, $g' = N_{\mathbb{K}/\mathbb{L}}(g)$, and $h' = N_{\mathbb{K}/\mathbb{L}}(h)$, then (f', g') is a vector of $\Lambda_{h'}^q$, and it may be an unusually short one.

n	$\log q$	r	$\ f\ $	$\sqrt{2/3 \cdot n}$	$\ f'\ $	$\left(\sqrt{2/3 \cdot n}\right)^r$
256	300	8	3.70893	3.70752	29.21967	29.66015
256	300	32	3.66546	3.70752	103.69970	118.64060
256	300	64	3.71731	3.70752	210.20853	237.28120

Table 1: Observed norms, after relative norm operation. All norms are logs.

1. NORMING DOWN

We assume that the following lemma holds also for all reasonable distributions considered in cryptographic constructions:

Let f be sampled from spherical Gaussians of variance σ^2 . Then,

$$\|f^r\| \leq \sqrt{n}^{r-1} \cdot \|f\|^r$$

2. LATTICE REDUCTION IN THE SUBFIELD

Run lattice reduction with block size β on lattice $\Lambda_{h'}^q$, to obtain a vector $(x', y') \in \Lambda_{h'}^q$, with

THE RIGHT KIND OF (x', y')

(x', y') is a solution in the subfield, how could that be useful?

THE RIGHT KIND OF (x', y')

(x', y') is a solution in the subfield, how could that be useful?

1. If (x', y') is short enough, then it is an \mathcal{R}' -multiple of (f', g') .
2. This will allow us to lift (x', y') to a short vector in Λ_h^q .

$$(x', y') = v \cdot (f', g')$$

Theorem

Let $f', g' \in \mathcal{R}'$ be such that $\langle f' \rangle$ and $\langle g' \rangle$ are coprime ideals and that $h' \cdot f' = g' \pmod{q}$ for some $h' \in \mathcal{R}'$. If $(x', y') \in \Lambda_h^q$, has length verifying

$$\|(x', y')\| < \frac{q}{\|(f', g')\|},$$

then $(x', y') = v \cdot (f', g')$ for some $v \in \mathcal{R}'$.

3. LIFTING THE SHORT VECTOR

To lift the solution from the sub-ring \mathcal{R}' to \mathcal{R} compute (x, y) as

- $x = L(x')$ and
- $y = L(y') \cdot h / L(h') \bmod q,$

where L is the canonical inclusion map.

Can solve in time complexity $\text{poly}(n) \cdot 2^{\Theta(\beta)}$ when

- **Direct lattice attack:** $\beta / \log \beta = \Theta(n / \log q)$

Can solve in time complexity $\text{poly}(n) \cdot 2^{\Theta(\beta)}$ when

- **Direct lattice attack:** $\beta / \log \beta = \Theta(n / \log q)$
- **Subfield attack:** $\beta / \log \beta = \Theta(n \log n / \log^2 q)$ whenever $r = \Theta(\log q / \log n) > 1$
